CALCIUM BLOCKERS TO TREAT PROLIFERATIVE **RETINAL DISEASES**

CROSS REFERENCE TO RELATED APPLICATIONS

5 This patent application is a continuation-in-part of U.S. Patent Application Serial No. 10/436,902, filed on May 12, 2003, which is a continuation of U.S. Patent Application Serial No. 10/038,215, filed on January 2, 2002, which is a continuation of U.S. Patent Application Serial No. 09/445,832 which was filed on December 13, 1999 as the U.S. National Patent Application of 10 PCT/US98/12414, which was filed on June 15, 1998 and was based on U.S. Provisional Application 60/051,962, which was filed on June 30, 1997 in the name of Dreyer for CALCIUM BLOCKERS TO TREAT PROLIFERATIVE VITREORETINOPATHY. All of the aforementioned patent applications are expressly incorporated by reference herein.

15

FIELD OF THE INVENTION

This invention relates to the treatment of diseases related to the proliferation or migration of retinal pigment epithelium and/or glial cells.

20

25

BACKGROUND OF THE INVENTION

Many diseases or conditions which threaten a person's vision are believed to be related to the migration or proliferation of retinal pigment epithelium and/or glial cells. Some examples of such diseases are nonexudative age related macular degeneration, exudative age related macular degeneration, choroidal neovascularization, acute macular neuroretinopathy, cystoid macular edema, diabetic macular edema, Behcet's disease, diabetic retinopathy, retinal arterial occlusive disease, central retinal vein occlusion, 30 uveitic retinal disease, retinal detachment, trauma, conditions caused by laser treatment, conditions caused by photodynamic therapy, photocoagulation, radiation retinopathy, epiretinal membranes, proliferative diabetic retinopathy, branch retinal vein occlusion, anterior ischemic optic neuropathy, nonretinopathy diabetic retinal dysfunction, and retinitis pigmentosa.

BRIEF DESCRIPTION OF THE INVENTION

We have discovered that glutamate causes migration and proliferation of retinal pigment epithelium and/or glial cells. The use of glutamate antagonists to reduce or control retinal pigment epithelium and/or glial migration and the subsequent development of diseases or conditions is disclosed herein.

Disclosed herein is a method of treating a disease or condition wherein migration or proliferation of retinal pigment epithelium or glial cells causes or contributes to the cause of said disease or condition, comprising administering a therapeutically effective amount of a compound which is a glutamate agonist to the patient suffering from said disease or condition.

DETAILED DESCRIPTION OF THE INVENTION

15

20

25

30

In relation to the methods of treating disclosed herein, the disease or condition being treated is a disease or condition wherein migration or proliferation of retinal pigment epithelium or glial cells causes or contributes to the cause of said disease or condition. The relationship may be direct or indirect, and the migration or proliferation retinal pigment epithelium or glial cells may be a root cause of said disease or condition, or may be a symptom of another underlying disease or condition. While not intending to limit the scope of the invention in any way, the following are examples of the types of diseases or conditions treated by the disclosed method: non-exudative age related macular degeneration, exudative age related macular degeneration, choroidal neovascularization, acute macular neuroretinopathy, cystoid macular edema, diabetic macular edema, Behcet's disease, diabetic retinopathy, retinal arterial occlusive disease, central retinal vein occlusion, uveitic retinal disease, retinal detachment, trauma, conditions caused by laser treatment, conditions caused by photodynamic therapy, photocoagulation, radiation retinopathy, epiretinal

membranes, proliferative diabetic retinopathy, branch retinal vein occlusion, anterior ischemic optic neuropathy, non-retinopathy diabetic retinal dysfunction, and retinitis pigmentosa.

5

10

15

20

25

30

In one method, disease or condition is selected from the group consisting of non-exudative age related macular degeneration, exudative age related macular degeneration, choroidal neovascularization, acute macular neuroretinopathy, cystoid macular edema, diabetic macular edema, Behcet's disease, diabetic retinopathy, retinal arterial occlusive disease, central retinal vein occlusion, uveitic retinal disease, retinal detachment, trauma, conditions caused by laser treatment, conditions caused by photodynamic therapy, photocoagulation, radiation retinopathy, epiretinal membranes, branch retinal vein occlusion, anterior ischemic optic neuropathy, non-retinopathy diabetic retinal dysfunction, and retinitis pigmentosa.

In another embodiment the disease or condition is not proliferative vitreoretinopathy.

In another method, the disease is proliferative diabetic retinopathy.

While not desiring to be bound to any specific theory, we conclude that one or more of the several types of calcium-permeable CNS ion channels mentioned below can be involved in controlling such migration, including: a) the various aspects of the NMDA (N-methyl-D-aspartate) receptor channel complex; b) the voltage-dependent Ca.sup.2+ channels; and c) other channels directly coupled to glutamate (or excitatory amino acid) receptors. Such channels are reviewed in: Sommer, B. and Seeburg, P. H. "Glutamate receptor channels: novel properties and new clones" Trends Pharmacological Sciences 13:291-296 (1992); Nakanishi, S., "Molecular Diversity of glutamate receptors and implications for brain function", Science 248:597-603 (1992).

The compound may be one of the so-called NMDA antagonists--i.e., it reduces neuronal damage mediated by the NMDA receptor complex.

Alternatively, the compound antagonizes neuronal damage mediated by the voltage-dependent calcium channel. Other useful compounds are those which limit release of glutamate from cells or reduce the intracellular neurotoxic

consequences of glutamate interaction with cell membrane glutamate receptors. Preferably, the compound crosses the blood-retinal barrier.

Particularly preferred compounds are antagonists of the NMDA receptor-channel complex. The term "NMDA receptor antagonists" includes several sub-types of NMDA antagonists including: a) channel blockers--i.e., antagonists that operate uncompetitively to block the NMDA receptor channel; b) receptor antagonists--antagonists that compete with NMDA to act at the NMDA binding site; c) agents acting at either the glycine co-agonist site or any of several modulation sites such as the zinc site, the magnesium site, the redox modulatory site, or the polyamine site; d) agents which inhibit the downstream effects of NMDA receptor stimulation, such as agents that inhibit activation of protein kinase C activation by NMDA stimulation, antioxidants, and agents that decrease phosphatidylinositol metabolism.

5

10

15

20

25

30

Other compounds that are useful in the invention include voltage-dependent calcium channel antagonists, e.g. those which exert a substantial direct effect on glutamate toxicity mediated by the L-type voltage dependent Ca.sup.++ channel in that they produce a statistically significant result in experiments measuring glutamate induced effects by the general method described in Karschian and Lipton, J. Physiol.418:379-396 (1989) or by other techniques for measuring antagonism of the L-type Ca.sup.++ channel known to those in the art. (We contrast the direct effect so measured with the secondary effects of excitoxicity mediated by other channels, which in turn causes flow through the voltage dependent Ca.sup.++ channels.) Particular candidate compounds include Class I voltage dependent Ca.sup.++ channel antagonists, e.g., phenylalkylamines.

Preferably, the compounds used cross the blood-retina barrier and can be administered chronically. Other useful agents act as antagonists of non-NMDA receptors (glutamate receptor types other than the NMDA receptor complex discussed above), and include agents which block inotropic glutamate receptors

or interact with metabotropic glutamate receptors (Nakanishi, supra). Still other agents act to limit (reduce) release of glutamate from cells, thereby acting upstream from the glutamate receptors in the excitatory neurotoxicity process. Still other agents may act by blocking downstream effects of glutamate receptor stimulation, e.g., the intracellular consequences of glutamate interaction with a cell membrane glutamate receptor, such as agents (like dantrolene) that block the rise in intracellular calcium following stimulation of membrane glutamate receptors.

5

20

25

30

The most preferred compounds are those capable of crossing the bloodretinal barrier; these compounds may be administered orally, intravenously, or
topically and cross intervening barriers including the blood-retina barrier to
reach the retinal ganglion cells. Compounds that do not freely cross the bloodretina barrier are less preferred; these compounds may be administered
intravitreally to the retina. In the case of compounds that have an intermediate
ability to cross the blood-retina barrier, the mode of administration will depend
on the dosage required and other factors.

Among the preferred compounds are amantadine derivatives (e.g., memantine, amantadine, and rimantadine), nitroglycerin, dextorphan, dextromethorphan, and CGS-19755. See generally, the compounds listed in Table 2.

The invention is useful for the reduction or prevention (including prophylactic treatment) of damage as a result of proliferative vitreoretinopathy.

In view of our discovery that glutamate is associated with proliferative vitreoretinopathy, the invention features antagonists having certain specific characteristics: the ability to cross the blood-retina barrier; and the ability to be administered chronically. Within those guidelines, any suitable antagonist of the glutamate induced excitotoxicity may be used in accordance with the invention. As mentioned, in preferred embodiments, N-methyl-D-aspartate (NMDA) subtype of glutamate receptor-channel complex may be used to reduce or prevent proliferative vitreoretinopathy-related injury. Many antagonists of the

NMDA receptor have been identified (Watkins et al., Trends in Pharmacological Sci. 11:25, 1990, hereby incorporated by reference). There are several recognized sub-types of NMDA receptor including: a) channel blockers-i.e., antagonists that operate non-competitively to block the NMDA receptor channel; b) receptor antagonists--antagonists that compete with NMDA, acting at the NMDA binding site; c) agents acting at either the glycine co-agonist site or any of several modulation sites such as the zinc site, the magnesium site, the redox modulatory site, or the polyamine site; d) agents which inhibit the downstream effects of NMDA receptor stimulation such as agents that inhibit activation of protein kinase C activation by NMDA stimulation, antioxidants, and agents that decrease phosphatidylinositol metabolism.

5

10

15

20

25

Other compounds that are useful in this invention include non-NMDA receptor antagonists, such as agents which block other types of inotropic glutamate receptors or interact with metabotropic glutamate receptors; voltage-dependent calcium channel antagonists (against L, N, T, and P type channels) (Bean, B. P. Annu. Rev. Physiol. 51:367-384 (1989); Hess, P. Annu. Rev. Neurosci. 13:337-356 (1990)), and are described in greater detail below; and agents which act to decrease the release of glutamate, thereby acting upstream in the excitatory neurotoxicity process.

Table 1, below, lists various suitable NMDA and non-NMDA receptors which do not operate via the voltage-dependent Ca.sup.++ ion channel. Tables 2-4 list antagonists of the voltage dependent Ca.sup.++ channel, which can be used by themselves in connection with the first aspect of the invention, and which can also be used in combination with other antagonists in the second aspect of the invention.

In Vitro Assay

20

25

15

An antagonist may be tested for utility in the method of the invention by monitoring its effect on proliferative retinopathy as follows.

thioridazine

tricyclic antidepressents

Cultured fibroblasts will be injected into the vitreous of the rabbit eye. After two weeks, the degree of vitreopathy can be assessed histologically. At the time of the initial insult, the animals will be treated with the compound under consideration.

Such models are well known. A few examples (hereby incorporated by reference) included Kiumura et al. Human Gene Therapy, 7:799-808 (1996); Sakamoto et al., Ophthalmology 102:1417-1421 (1995); Handa et al. Experimental Eye Research 62:689-696 (1996); Berger et al. 37:2318-1325 (1996); de Souza et al. Ophthalmologica 209:212-216 (1995); Nakagawa et al. Ophthalmology & Visual Science 36:2388-2395 (1995); Steinhorst et al. Archive for Clinical & Experimental Ophthalmology 232:347-354 (1994).

Use

An effective receptor antagonist will cause a decrease in proliferative vitreoretinopathy. As described above, the preferred compounds which cross the blood-retinal barriers are preferably administered topically or orally in known, physiologically acceptable vehicles including tablets, liquid excipients and suspensions. Those skilled in the art will appreciate how to formulate acceptable therapeutics.

10

15

5

Antagonists may be compounded into a pharmaceutical preparation, using pharmaceutical compounds well-known in the art; the exact formulation and dosage of the antagonist compound depends upon the route of administration. Generally, the effective daily dose of the antagonists will range from 0.01 to 1000 mg/kg.

Other Embodiments

Other embodiments are within the following claims. In the method of the
invention, a useful compound may be administered by any means that allows
the compound access to the retina. The compounds useful in the method include
antagonists of excitatory amino acid receptors (both NMDA and non-NMDA
subtypes) that act to reduce retinal cell migration or proliferation or reduce
binding of glutamate to the NMDA receptor. The antagonists can act at a
modulatory site or a co-agonist site or by blocking the chain of events initiated
by receptor activation.
